ABSTRACT

Finding a minimum spanning tree (MST) is a fundamental graph algorithm with applications in many fields. This paper presents ECL-MST, a fast MST implementation designed specifically for GPUs. ECL-MST is based on a parallelization approach that unifies Kruskal's and Borůvka's algorithm and incorporates new and existing optimizations from the literature, including implicit path compression and edge-centric operation. On two test systems, it outperforms leading GPU and CPU codes from the literature on all of our 17 input graphs from various domains. On a Titan V GPU,

lines. In this example, the cheapest distribution grid that allows everyone to deliver or receive electricity is the MST shown.

SC'23

Current status

Irregular Mem. access

Poly-time Problems

- Parallelization is easier
- Algorithms are simpler
- Run few seconds on million/billion-scale
- Solution search space is small
- Exact solution

Examples

- Minimum Spanning Tree
- Single Source Shortest Path

Goal: Solve largest benchmark instances from DIMACS/PACE Challenges

NP-Hard Problems

- Comparitively difficult
 - Complicated algorithms
 - Few hours for thousand-sized instances
 - Solution search space is large
 - Tradeoff: Solution vs Time
-
- Steiner Tree Problem
 - Travelling Salesman Problem
 - Vehicle Routing Problem
-
- More practical applications

Algorithms and Optimizations

- Parallel Implementations chosen from
 - Efficient serial algorithm
 - Proven algorithm amenable for parallelization

Design parallelism-friendly algorithms

- Optimizations

Peak performance

Data-driven versus Topology-driven Irregular Computations on GPUs

(a topology counterhala In this p implementation goal is to um and how to generally fa a worklist, when certain implementat that combin
Keywords: i algorithmic

Abstract—The performance of graph programs depends highly on the algorithm, the size and structure of the input graphs, as well as the features of the underlying hardware. No single set of optimizations or one hardware platform works well across all settings. To achieve high performance, the programmer must carefully select which set of optimizations and hardware platforms to use. The GraphIt programming language makes it easy for the programmer to write the algorithm once and optimize it for different inputs using a scheduling language. However, GraphIt currently has no support for generating high-performance code for GPUs. Programmers must resort to re-implementing the entire algorithm from scratch in a low-level language with an entirely different set of abstractions and optimizations in order to achieve high performance on GPUs.

We propose G2, an extension to the GraphIt compiler framework, that achieves high performance on both CPUs and GPUs using the same algorithm specification. G2 significantly expands the optimization space of GPU graph processing frameworks with a novel GPU scheduling language and compiler that enables combining load balancing, edge traversal direction, active vertexset creation, active vertexset processing ordering, and kernel fusion optimizations. G2 also introduces two performance optimizations, Edge-based Thread Warps CTAs load balancing (ETWC) and EdgeBlocking, to expand the optimization space for GPUs. ETWC improves load balancing by dynamically partitioning the edges of each vertex into blocks that are assigned to threads, warps, and CTAs for execution. EdgeBlocking improves the locality of the program by reordering the edges and restricting random memory accesses to fit within the L2 cache. We evaluate G2 on 5 algorithms and 9 input graphs on both Pascal and Volta generation NVIDIA GPUs, and show that it achieves up to 5.11x speedup over state-of-the-art GPU graph processing frameworks, and is the fastest on 66 out of the 90 experiments.

Index Terms—Compiler Optimizations, Graph Processing, GPUs, Domain-Specific Languages

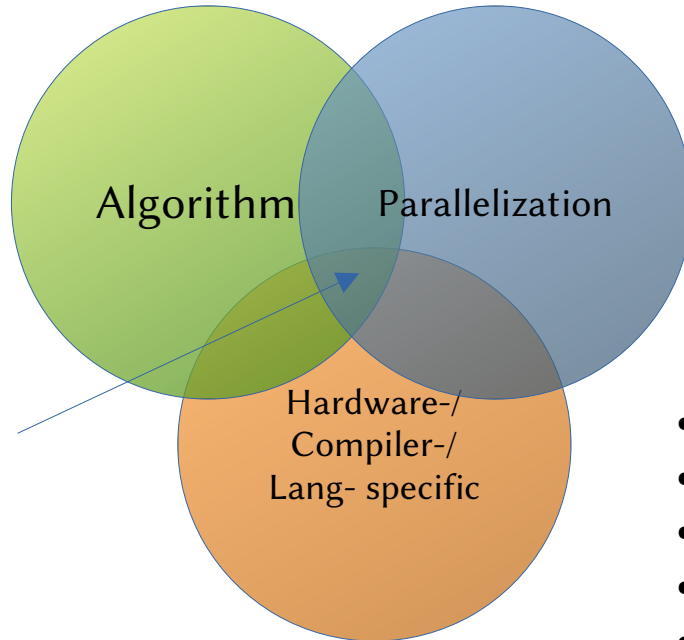

Fig. 1. G2 adds a new GPU backend to GraphIt that produces CUDA from the same GraphIt algorithm language and a scheduling language tail for GPU optimizations.

In prior work, we built the GraphIt DSL compiler [7] to generate high-performance CPU code from a high-level algorithm language. GraphIt achieves state-of-the-art performance on CPUs across different algorithms and graph inputs by introducing a scheduling language to tune optimizations. The algorithm language has primitives for topology-driven algorithms, data-driven algorithms, and priority-based algorithms. This algorithm and schedule representation makes it easy for the programmer to write an algorithm once and generate different highly-optimized implementations by simply changing the schedule. We will discuss in detail the GraphIt algorithm and scheduling languages in Section IV.

Apart from a large body of work for optimizing algorithms on different inputs on CPUs [6], [8], [9], [10], [11], [13], [14], [15], researchers have also used different hardware platforms for high-performance graph processing, including GPUs [16], [17], [18], [19], [20], [21], [22], [23], [24], [25], [26], [27], [28], [29], [30], [31], [32], [33], [34], [35], [36], [37], [38], [39], [40], [41], [42], [43], [44], [45], [46], [47], [48], [49], [50], [51], [52], [53], [54], [55], [56], [57], [58], [59], [60], [61], [62], [63], [64], [65], [66], [67], [68], [69], [70], [71], [72], [73], [74], [75], [76], [77], [78], [79], [80], [81], [82], [83], [84], [85], [86], [87], [88], [89], [90].

Optimizing for peak performance

- Input Characteristics
 - Diameter
 - Max degree
 - Road/social network
- Properties of substeps

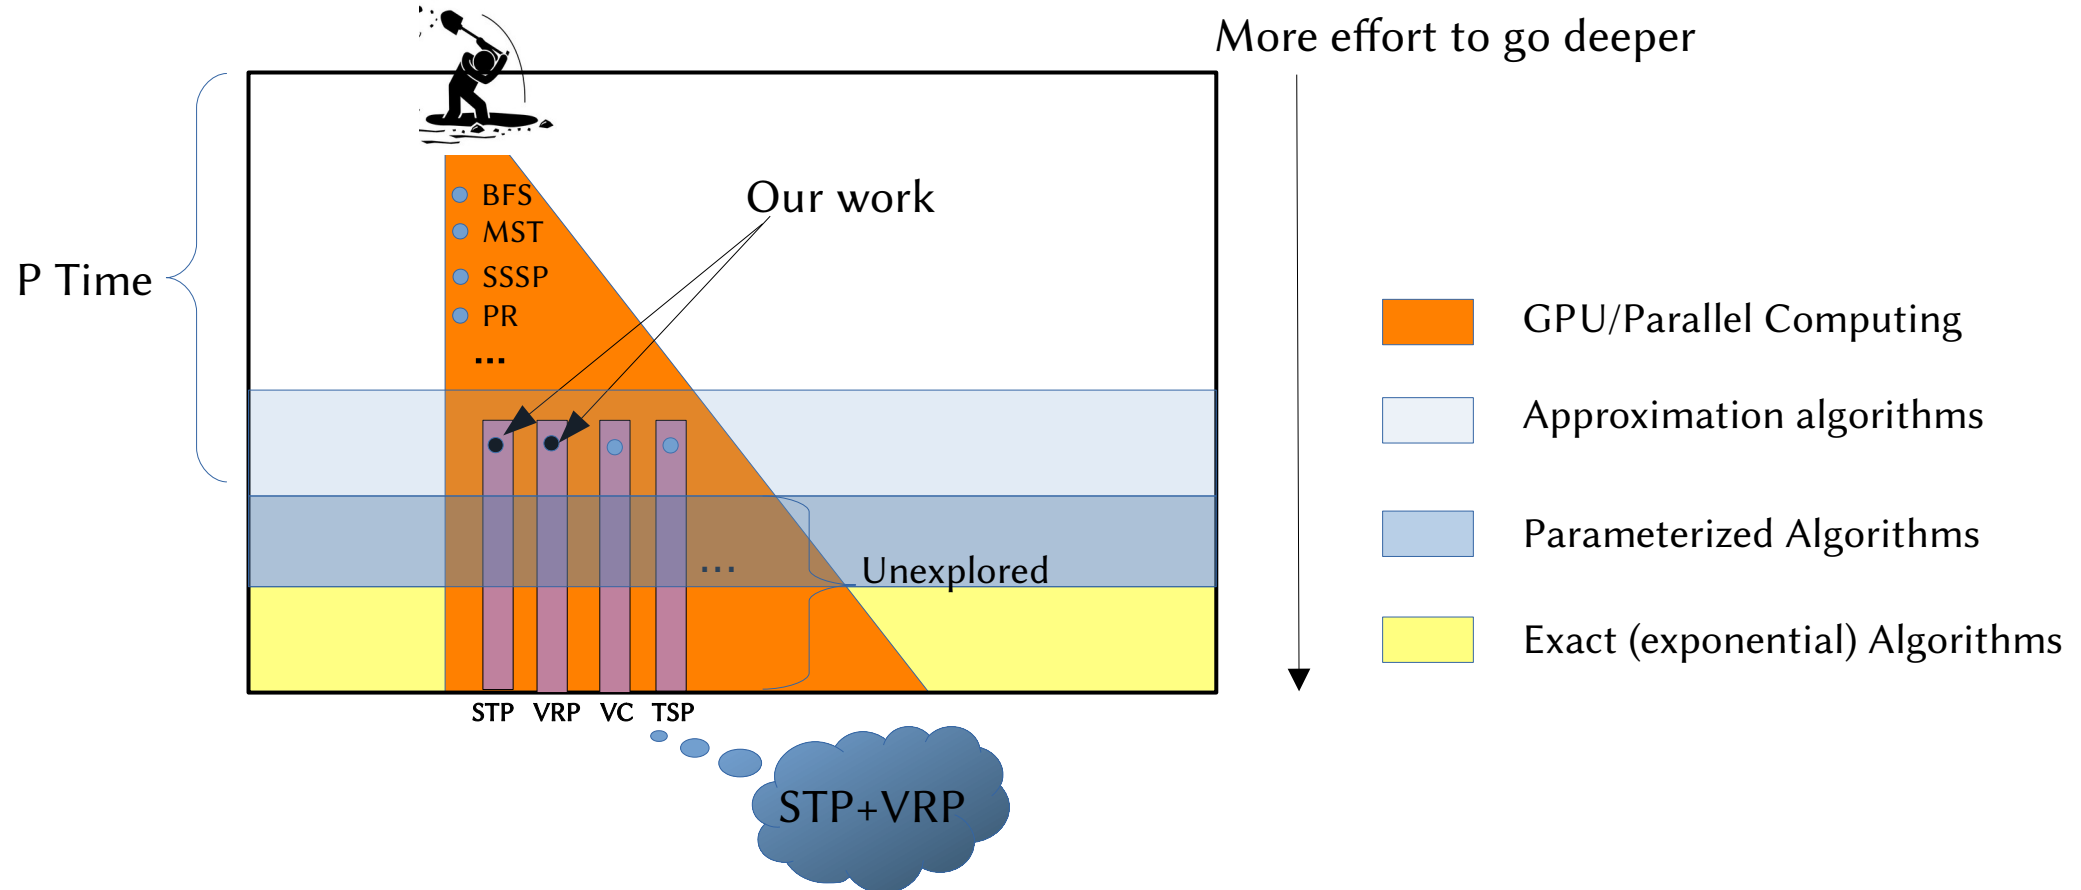

Peak performance

- Vertex-/Edge- centric
- Data-/Topology-driven
- Push-/Pull-based
- Load-balancing
- ...

- Architecture-specific
- Shared memory
- Warp-Intrinsics
- Data accesses within reg/caches
- Vectorization loads/adds

- Use profilers and <https://godbolt.org>

Landscape of Parallelization

Steiner Tree - Example

- Let's say Highway Department wants to add more lanes to connect K, M and C
- Say K, M & C are important.
- Overall budget should be minimum
- Budget \propto Distance

Steiner Tree Problem (STP) – Example

Input : Graph $G(V, E, W)$ $W:E \rightarrow \mathbb{Z}^+$ and $L \subseteq V$ terminals.

Output: A tree $T'(V' \supseteq L, E' \subseteq E)$ of G such that minimize $W(E')$.

// Minimum weighted tree with all terminals.

Fig 1 (a)

Fig 1 (b)

● Terminals
● Non-terminals

Steiner Tree Problem (STP) – Example

Input : Graph $G(V, E, W)$ $W:E \rightarrow \mathbb{Z}^+$ and $L \subseteq V$ terminals

Output : Minimum weighted tree with all terminals

Fig 2 (a)

Fig 2 (b)

$|MST| = 37$
 $|OPT| = 18$

● Terminals
● Non-terminals

Steiner Tree Problem (STP) - Hardness

Input : Graph $G(V, E, W)$ $W:E \rightarrow \mathbb{Z}^+$ and $L \subseteq V$ terminals

Output : Minimum weighted tree with all terminals

Take away

- MST solution is a valid feasible Steiner Tree solution
- However, solution can be arbitrarily bad w.r.t OPT.

Special cases

- $L = \{u, v\}$ or $k = 2$ STP=ShortestPath_In_G(u, v)
- $L = V$ or $k = n$ STP=MST(G)
- In general STP is NP-Hard

How to deal with NP-Hardness

- What could be naive solutions? Enumerate all Spanning trees.

Approximation algorithm

- Runs in Polynomial time.
- Outputs an approximate solution with some guarantee.
 - e.g 2 or some constant, $\log n$, etc.
- There are several algorithms
 - Kou, Markowsky and Berman [KMB81]
 - Mehlhorn [M88]
 - Robins and Zelikovsky [RZ2000]

$$|ALG| \leq 2 |OPT|$$

KMB

L. Kou, G. Markowsky, and L. Berman. A fast algorithm for Steiner trees. *Acta Informatica*, 1981.

KMB Algorithm $G(V,E,W,L)$

Phase 1

// Input G

Computes the shortest distance between every pair of terminals

Phase 2

// Construct $G' = K_L$

Build a graph G' over terminals, having edge-weights corresponding to the shortest distances computed in Phase 1

// Every edge in G' corresponds to a path in G

$MST(G')$

Phase 3

// Construct G''

For every edge in $MST(G')$ substitute the edges with the corresponding shortest path in G

// Collect all the edges & vertices of the corresponding path to construct G''

$MST(G'')$

Takeaway: One more invocation for SSSP/MST algorithm. $G \rightarrow G' \rightarrow G''$

KMB Algorithm – Running example

1) A parallel KMB may output a different answer. (2) Last MST may be avoided

Fig. 3 Execution steps of KMB algorithm, where ● are terminals and ● are non-terminals.

KMB Algorithm $G(V, E, W, L)$

Phases 1 & 2

```

For u in L {
  For v in L {
     $P_{uv} = \text{ShortestPath}(u, v)$ 
     $W'(u, v) = |P_{uv}|$ 
  }
}
T' = \text{MST}(G', W')
```

Observe:
Two For-loops.
Naive?

Phase 3

```

For (u,v) in edges of  $T'$  {
   $G'' = G'' \cup P_{uv}$ 
  //Add vertices & edges of  $P_{uv}$ 
}

 $T'' = \text{MST}(G'', W)$ 
```

KMB Algorithm $G(V, E, W, L)$

Input: Graph $G(V, E, W, L)$

Output: 2-approx Steiner Tree $T(V_T, E_T)$ $V_T \supseteq L$

For $u \in L$ {

SSSP(G, W, L, u) with Halt

Compute W' incrementally

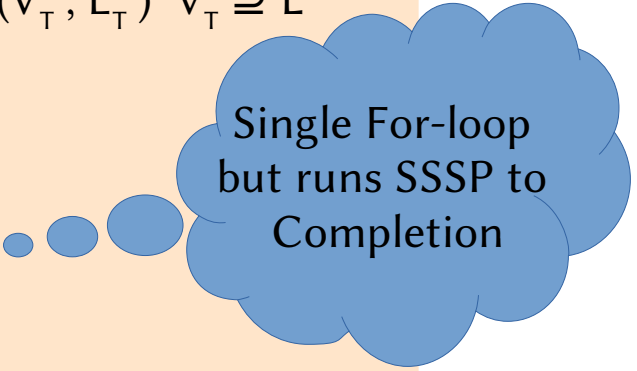

}

$T' = \text{MST}(G', W')$

Compute G'' and its vertices, adjList using T'

$T'' = \text{MST}(G'', W)$

return T''

Single For-loop
but runs SSSP to
Completion

CPU Implementation - Optimization

- SSSP-halt optimization

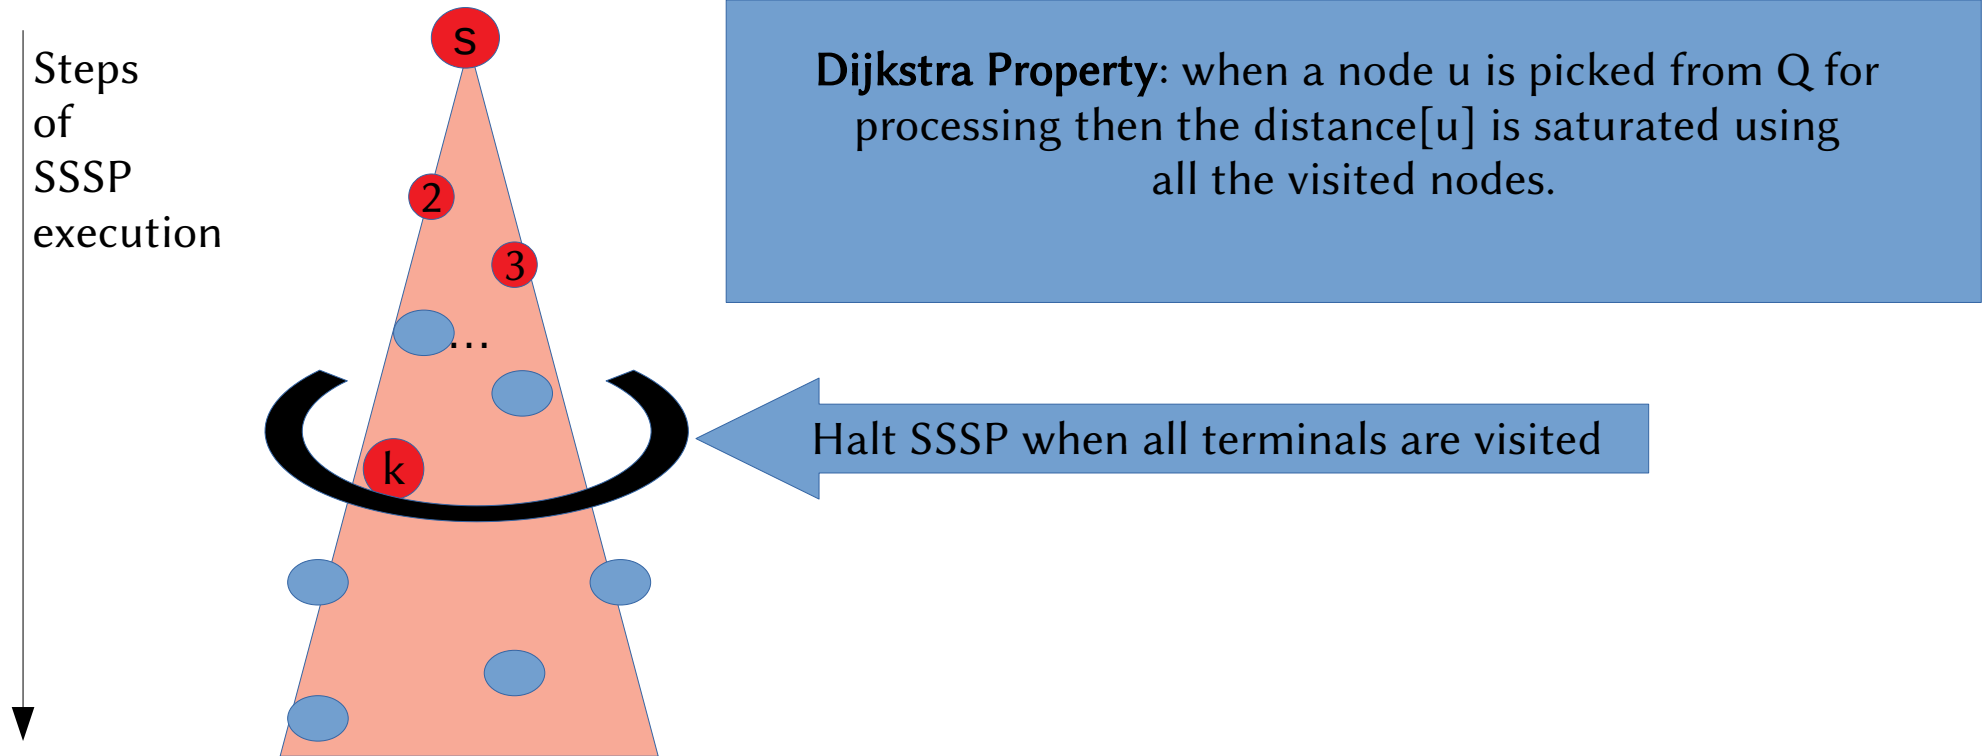

Fig. 4 SSSP-halt visualization

KMB Algorithm $G(V, E, W, L)$

Input: Graph $G(V, E, W, L)$

Output: 2-approx Steiner Tree $T(V_T, E_T) \ V_T \supseteq L$

For $u \in L$ {

parallel SSSP(G, W, L, u);

Compute W' incrementally;

}

$T' =$ **parallel** MST(G', W');

Compute G'' and its vertices, adjList ;

$T'' =$ **parallel** MST(G'', W);

return T''

A novel aspect of our work is to run multiple parallel-SSSPs in parallel.

Subroutines?
Gunrock

Design choice for parallelization

Fig. 5 Sequential vs GPU v1 vs GPU v2

KMBCPU
KMBGPU

GPU Implementation - SSSP

- n-threads
- One thread for each node
- Performs RELAX in parallel
- RELAXes its neighbours
- Till there is no change

Fig. 6 push-SSSP

KMB Algorithm $G(V,E,W,L)$

MAIN

```

For s in L {
  ThdsPerBlk = 512; // or 1024
  Blks =  $\lceil n / \text{ThdsPerBlk} \rceil$ ;
  do {
    INIT-KERNEL<Blks,ThdsPerBlk>(s,  $d_s$ ,  $p_s$ , n);
    RELAX-KERNEL<Blks,ThdsPerBlk>(.., s,  $d_s$ ,  $p_s$ , changed, n);
    CopyTo(DArray,  $d_s$ );           // = = = = =
    CopyTo(PArray,  $p_s$ );           // From Device to Host
    CopyTo(hChanged, changed); // = = = = =
  } while (hChanged);
}

```

- We need the $p[]$ for knowing the intermediate vertices in the shortest path

KMB Algorithm $G(V,E,W,L)$

```
RELAX-KERNEL(..,s, ds, ps, changed, n) {  
  u = tid // compute tid;  
  If tid < n {  
    For v ∈ adjacent[u] { // Using CSR arrays  
      // Relax Operation (u, v, W(u,v))  
      newCost = ds[u] + W(u, v);  
      old = ds[v];  
      If newCost < old  
        Atomic-MIN(ds[v], newCost);  
      // Updates Parent array  
      If Atomic-MIN is success {  
        ps[v] = u;  
        changed = true;  
      }  
    }  
  }  
}
```

Note :

- Parent of v should be updated if the Atomic-MIN is success

Is it enough?

Parent update - Challenge

<snip>

..

$\text{newCost} = d_s[u] + W(u, v);$

$\text{old} = d_s[v];$

If $\text{newCost} < \text{old}$

Atomic-MIN($d_s[v]$, newCost);

// Updates Parent array

If Atomic-MIN is success {

$p_s[v] = u;$

changed = **true**;

}

</snip>

Fig. 7 Challenges in parent update

Even **Gunrock** has a challenges in updating p array consistently.
Listed as known issues <https://github.com/gunrock/gunrock/releases/tag/v1.0>

Parent update - Challenge

Shared
d[], p[]

Thread 1

newCost=7
old=10

d[v]=7 //oldA=10

p[v] = 1.

Wrong!

Thread 2

newCost=5
old=10

d[v]=5 //oldA=7

p[v]=2

<snip>

```
newCost = d[u] + W (u, v) ;
old = d[v];
```

```
If newCost < old
    oldA=Atomic-MIN(d[v], newCost);
```

```
// Update's Parent array
```

```
If Atomic-MIN is success {
```

```
    p[v] = u;
    changed = true;
```

```
}
```

It is a challenge to find which “thread” updated d[v] to the minimum

How to update both distance and parent at the same time?

Synchronization optimization • Pull

Fig. 8 Pull-SSSP

Because, one thread is writing to an index

GPU Optimizations

- Synchronization
 - Push
 - Pull
- Computation
 - Data-driven
 - Edge-based
 - Controlled Computation unrolling
 - Δ^2
 - 2Δ
 - $t\Delta$
- Memory
 - Shared memory

Δ – max degree of the graph

GPU Optimizations

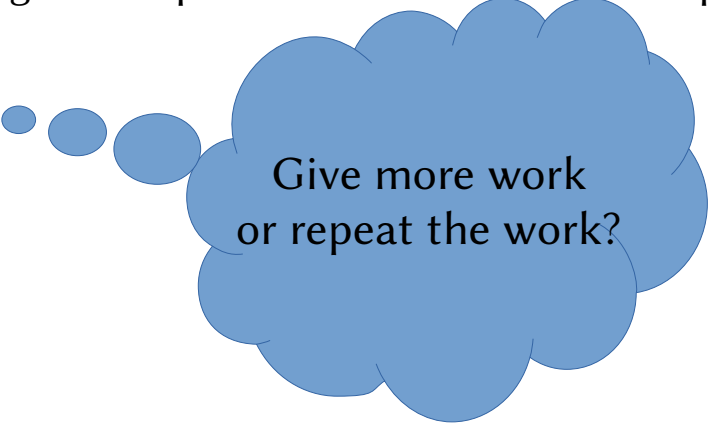

- Synchronization
 - Push
 - **Pull**
- Computation
 - Data-driven
 - Edge-based
 - **Controlled Computation unrolling**
 - Δ^2
 - 2Δ
 - **$t\Delta$**
- Memory
 - **Shared memory**

Δ – max degree of the graph

Compute optimization

- Computation Unrolling
 - Instead of one thread doing Δ work, perform more work per thread
 - Update also neighbours of neighbours (Δ^2)
 - **Repeat the work**; Say 2 times or t times (2Δ or $t\Delta$); e.g. we do pull 3 times in the kernel – 3-pull
- Data-driven
 - Needs Worklist (WL)
 - Active/Change nodes are inserted into WL
- Edge-based optimization
 - m -threads are launched
 - RELAXes one edge or a group of edges

Give more work
or repeat the work?

Memory optimization

- Programmable shared memory can be useful
- When there are multiple reads to DRAM
- We can move data to shared memory
- For e.g. In 3-pull, we moved CSR AdjList to shared
- As the neighbours AdjList is accessed 3 times
- Of the total 48K per block
- when using 512 threadPerBlock we have 24 words to store per thread
- Hence, if $\text{degree}(\text{node}) < 25$ we use shared, we move $\text{CSR AdjList}[\text{node}]$ to Shared
- With shared memory we achieve 25% of improvement in 3-pull

Double-barrel approach

- SSSP happens in parallel
- To run two SSSP, we have to run one after the other
- Instead we use Double-barrel approach
- This can be generalized (p-SSSP)

In our Double-barrel approach, we run two individually parallel SSSPs also in parallel.

Image source: <https://stock.adobe.com/>

Double-barrel approach

Result Array: $d[n]$

Initialize($d = \text{INTMAX}$)

$d[\text{src}] = 0$

FixedPoint{

doRELAX($G, d, \text{changed} \dots$);

}

Result Array: $d[2n]$

Initialize($d = \text{INTMAX}$)

$d[\text{src1}] = 0$; $d[n + \text{src2}] = 0$

FixedPoint{

doRELAX($G, \text{dist}, \text{changed}, \dots$);

}

Fig. 9 Double-barrel approach.

Tunable
arbitrary value

Key takeaways so far

- Solving Steiner Tree Problem is NP-hard
- KMB Algorithm, a 2-approximation algorithm
- CPU implementation has SSSP-halt optimization
- SSSP with parent array update was challenging
- Pull-based SSSP is great for KMBGPU even without SSSP-halt
- Parallel-SSSPs in parallel (p-SSSP)

Experimental setup & Graphsuite

CPU

- Intel(R) Xeon(R) E5-2640 v4 @ 2.40GHz
- 64GB RAM

GPU

- Tesla P100 @ 1.33 GHz
- 12GB global memory
-
- GCC 7.3.1 with O3
- CUDA 10.2

Graphsuite

- Total 14 Graphs
 - 11 from PACE Challenge [PACE2018]
 - 2 from SteinLib
 - 1 from SNAP

Baselines

- PACE'18 Winner – CIMAT [PACE2018]
- ODGF's KMB/JEA [BC19]

- CIMAT Team - <https://github.com/HeathcliffAC/SteinerTreeProblem>
- S. Beyer and M. Chimani, Strong Steiner Tree Approximations in Practice, JEA 2019.

Experiments: Speed-up

Fig. 10 Speed-up comparisons of the implementations (higher is better). JEA timed-out on t11

Takeaway: KMBCPU and KMBGPUOPT is better than JEA

Comparison of GPU time with Shared mem.

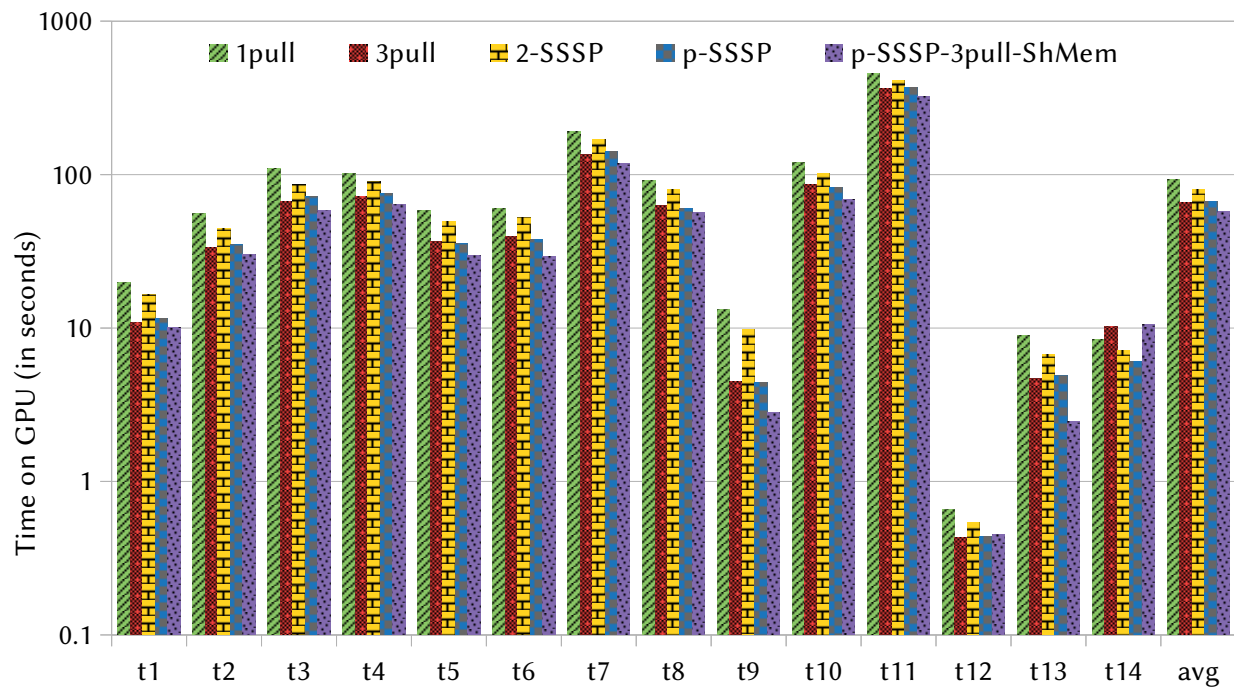

Fig. 11 Comparison of 1-Pull, 3-Pull, Double-barrel & KMBGPU-OPT

Takeaway: Combining GPU optimizations p-SSSP, 3-Pull & Shared memory performs best.

Comparison of p-SSSP

Fig. 12 KMBGPU with varying p-SSSP for the same graphs t14 (Smaller is better).

Takeaway: As we increase the #parallel SSSPs it reaches a point and then increases.

Experiments – Scalability of GPU and CPU

Fig. 13 Scalability plot on t14 with increasing terminal size (lower is better)

Takeaway: KMBGPU-OPT scales better than KMBCPU

Summary - STP

- Optimized CPU implementation for KMB algorithm
 - Novel SSSP-halt technique
 - Speed-up of 4x (average) over JEA/OGDF's KMB[BC19]
- Optimized GPU implementation for KMB algorithm
 - Novel p-SSSP technique (multiple parallel-SSSP in parallel)
 - Speed-up of 20x (average) over sequential JEA[BC19]

</work>

Capacitated Vehicle Routing Problem (CVRP)

Input : Given n nodes (single Depot and customers) with their coordinates (x_i, y_i) and demands $d_i > 0$ for $i \in n$, Vehicle capacity C . Node 0 is Depot and has zero demand.

Output: Set of routes serving all the customers respecting the vehicle capacity from/to Depot.

Goal : Minimize total distance travelled.

If Capacity = sum of demands d_i ,
CVRP → Travelling Salesman Problem

NP-Hard

CVRP Limitations

Current state-of-the-art

- work only on smaller instances
- has a large solution Gap
- takes a lot of time

Instance	Number of customers	Time (s)	
		Base2	Base1
Flanders2	30,000	8,355	2,534
Flanders1	20,000	7,768	2,031
Brussels1	15,000	7,164	871

Table 4: State-of-the-art GPU methods are time-consuming.

RQ1. Can we invent a simpler algorithm?

RQ2. Can we reduce Gap on large instances?

RQ3. Design Parallelization friendly algorithms?

Our ParMDS

- Serial and **Par**allel implementation

5     end
6 end
7 ...

```

Experiments

- 130 Instances of CVRPLIB
- Intel Xeon CPU E5-2640 v4
- Baselines on GPU
 - NVIDIA's Tesla P100
 - CUDA 11.5
- Our Code uses
 - **SeqMDS**: GCC 9.3.1
 - **ParMDS**: nvc++ compiler NVIDIA's HPC SDK 22.11

Speedup of ParMDS vs. baselines

Method	Execution Time (s) using Random
SeqMDS	1,722.44
ParMDS-Standard	1,522.26
ParMDS-Strided	186.50

More detailed analysis in our paper

Gap at the end of each step

Summary

- Fresh perspective to design parallelism-friendly algorithms
- Performance: Algorithmic-, Parallelism- & Platform- specific Optimizations
- Our techniques are applicable in general
 - Two-level parallelism (p-SSSP) technique
 - Strided parallel Local-search
- Promising future directions in our area (next 3-10 years)
 - Paradigm specific parallelization: Greedy, Dynamic Programming
 - Most STL algorithms would run parallel // My Prediction
 - Single source code for multi-core and GPU

Thank you!
